

Influence_Consensus_add_fam - In society, does addiction alone generally have a direct effect on the quality to Family Orientation, or are observed relationships primarily indirect? If a direct effect exists, is it negative, none, negligible, or positive? What would be a reasonable normalized magnitude for this influence on a scale from -1.00 to 1.00? Please only provide evidence for only direct influences.

Addiction alone has a direct negative effect on family orientation by disrupting family dynamics, emotional bonds, and value systems. Substance addiction often leads to family destabilization through shifts away from pro-family values toward greater individualization, weakening family ties and priorities (Pospíšil & Olecká, 2023). Families with addicted members experience significant psychological, economic, and social strain, which directly impairs family functioning and cohesion (Genç et al., 2023; Mardani et al., 2023). Clinical observations identify dysfunctional family models linked to addiction, such as performance-oriented families that deny emotional needs and affect-oriented families characterized by enmeshment, both of which contribute to the genesis and maintenance of addiction (Violino & Tunesi, 2025). Family-oriented treatment approaches show positive effects on both patients and family members, highlighting the importance of addressing these direct relational impacts in recovery (Kalsås et al., 2020). On a normalized scale from -1.00 to 1.00 representing direct influence on family orientation quality, addiction's effect would be negative and moderate to strong, reasonably estimated around -0.6 due to its substantial disruption of family structure and values (Genç et al., 2023; Pospíšil & Olecká, 2023; Mardani et al., 2023).
