

Influence_Consensus_agr_educ - In society, does Agriculture alone generally have a direct effect on the cost of education (excluding the accessibility to or quality of education), or are observed relationships primarily indirect? If a direct effect exists, is it negative, none, negligible, or positive? What would be a reasonable normalized magnitude for this influence on a scale from -1.00 to 1.00? Please only provide evidence for only direct influences

Agriculture alone does not have a clear direct causal effect on the cost of education; observed relationships are primarily indirect. For instance, agricultural productivity shocks, such as rainfall variations, influence household education expenditures mainly by affecting child labor decisions rather than directly altering education costs (Nordman et al., 2021). Studies on cost behavior in agricultural colleges focus on how enrollment affects costs but do not establish agriculture itself as a direct driver of education costs (Nefstead & Gillard, 2019). Research linking agricultural education spending to agricultural sector growth highlights investment in education but does not show agriculture directly changing the cost structure of education (Gasam, 2025). Agricultural exports impact youth education through increased child labor and reduced schooling years, indicating indirect effects mediated by economic factors rather than direct cost changes (Lin, 2021). Overall, the evidence suggests that agriculture's direct influence on the cost of education is negligible or none, with a reasonable normalized magnitude near 0.0 on a scale from -1.00 to 1.00.
